

TOF Problems For General Conics

Lambert's Example for Ellipse

A spacecraft is **observed** twice, **90° apart**, for which **h_1** is **2298 km**, & **h_2** is **6476 km**. If ' **a** ' is **12×10^6 m**, determine (1) **Δt** between two **observations** and (2) **e** .

$$r_1 = 6378 + 2298 = 8676 \text{ km}, \quad r_2 = 6378 + 6476 = 12584 \text{ km}$$

$$\theta = 90^\circ; \quad d = \sqrt{r_1^2 + r_2^2 - 2r_1r_2 \cos 90^\circ} = 15.5 \times 10^6 \text{ m},$$

$$a = 12 \times 10^6 \text{ m}, \quad \cos \alpha = 1 - \frac{r_1 + r_2 + d}{2a} = -0.5317;$$

$$\alpha = 2.145 \text{ rad}; \quad \cos \beta = 1 - \frac{r_1 + r_2 - d}{2a} = 0.75;$$

$$\beta = 0.724 \text{ rad}; \quad \sqrt{\frac{a^3}{\mu}} = 2082 \text{ s}, \quad \text{TOF} = 2580 \text{ s} = 43 \text{ min}$$

Lambert's Example for Ellipse

(2) **Eccentricity** of the orbit:

$$\psi = \alpha - \beta = 1.421 \text{ rad}, \quad \frac{\cos E_B}{\cos E_A} = \frac{a - r_2}{a - r_1} = \frac{-854000}{3324000}$$

$$\frac{\cos E_B}{\cos E_A} = -0.26; \quad \tan E_A = \frac{1}{\sin \psi} \left(\cos \psi - \frac{\cos E_B}{\cos E_A} \right)$$

$$\tan E_A = 0.4138, \quad E_A = 0.3923 \text{ rad}; \quad e = \frac{a - r_1}{a \cos E_A}$$

$$e = 0.2997$$

Lambert's Example for Parabola

An object is **sighted** twice at an angular separation of 170.5° at distances of **6378** km and **920,000** km respectively. If it is **known** that object is on a **parabolic** path, determine time **elapsed** between two **observations**.

$$\mu = 3.986 \times 10^{14} \text{ m}^2 / \text{s}^2$$

$$r_1 = 6.378 \times 10^6 \text{ m}; \quad r_2 = 9.2 \times 10^8 \text{ m}; \quad d = 9.26291 \times 10^8 \text{ m}$$
$$TOF = 665697 \text{ s} = 11094.9 \text{ min} = 184.9 \text{ h (Exact: 182.2 h)}$$

Lambert's Example for Hyperbola

An object is **sighted** twice at an angular **separation** of 135.5° at distances of **6378 km** and **920,000 km** respectively. If it is **known** that object is on a **hyperbolic** path, and has $a = -16.89 \times 10^6$ m, determine Δt .

$$\mu = 3.986 \times 10^{14} \text{ m}^2 / \text{s}^2$$

$$r_1 = 6.378 \times 10^6 \text{ m}; \quad r_2 = 9.2 \times 10^8 \text{ m}; \quad d = 9.2456 \times 10^8 \text{ m}$$

$$\sinh \frac{\alpha}{2} = 5.234; \quad \sinh \frac{\beta}{2} = 0.164; \quad \alpha = 4.7146; \quad \beta = 0.3265$$

$$TOF = 177513 \text{ s} = 2958.6 \text{ min} = 49.3 \text{ h}$$

Lambert's Example – 'a' Estimation

A spacecraft is **observed** twice, **90°** & 42.9 min **apart**, for which **h_1** is **2298 km**, & **h_2** is **6476 km**. Determine 'a'.

$$r_1 = 6378 + 2298 = 8676 \text{ km}, \quad r_2 = 6378 + 6476 = 12584 \text{ km}$$

$$d = 15.5 \times 10^6 \text{ m}, \quad r_1 + r_2 + d = 37.02 \times 10^6 \text{ m}; \quad r_1 + r_2 - d = 6.03 \times 10^6 \text{ m}$$

Lambert's Example – 'a' Estimation

Let us take a **guess** for 'a' midway between ' r_1 ' & ' r_2 ' as 10.8×10^6 m. With this, we get $\alpha = 2.36$ & $\beta = 0.765$, $(1/n) = 1778$ s and $\Delta t = \mathbf{46.9 \text{ min}}$.

Next, we take $\mathbf{a = 13 \times 10^6 \text{ m}}$, for which we get $\Delta t = \mathbf{40.6 \text{ min}}$. We can now set up an iteration **to refine it**.
